

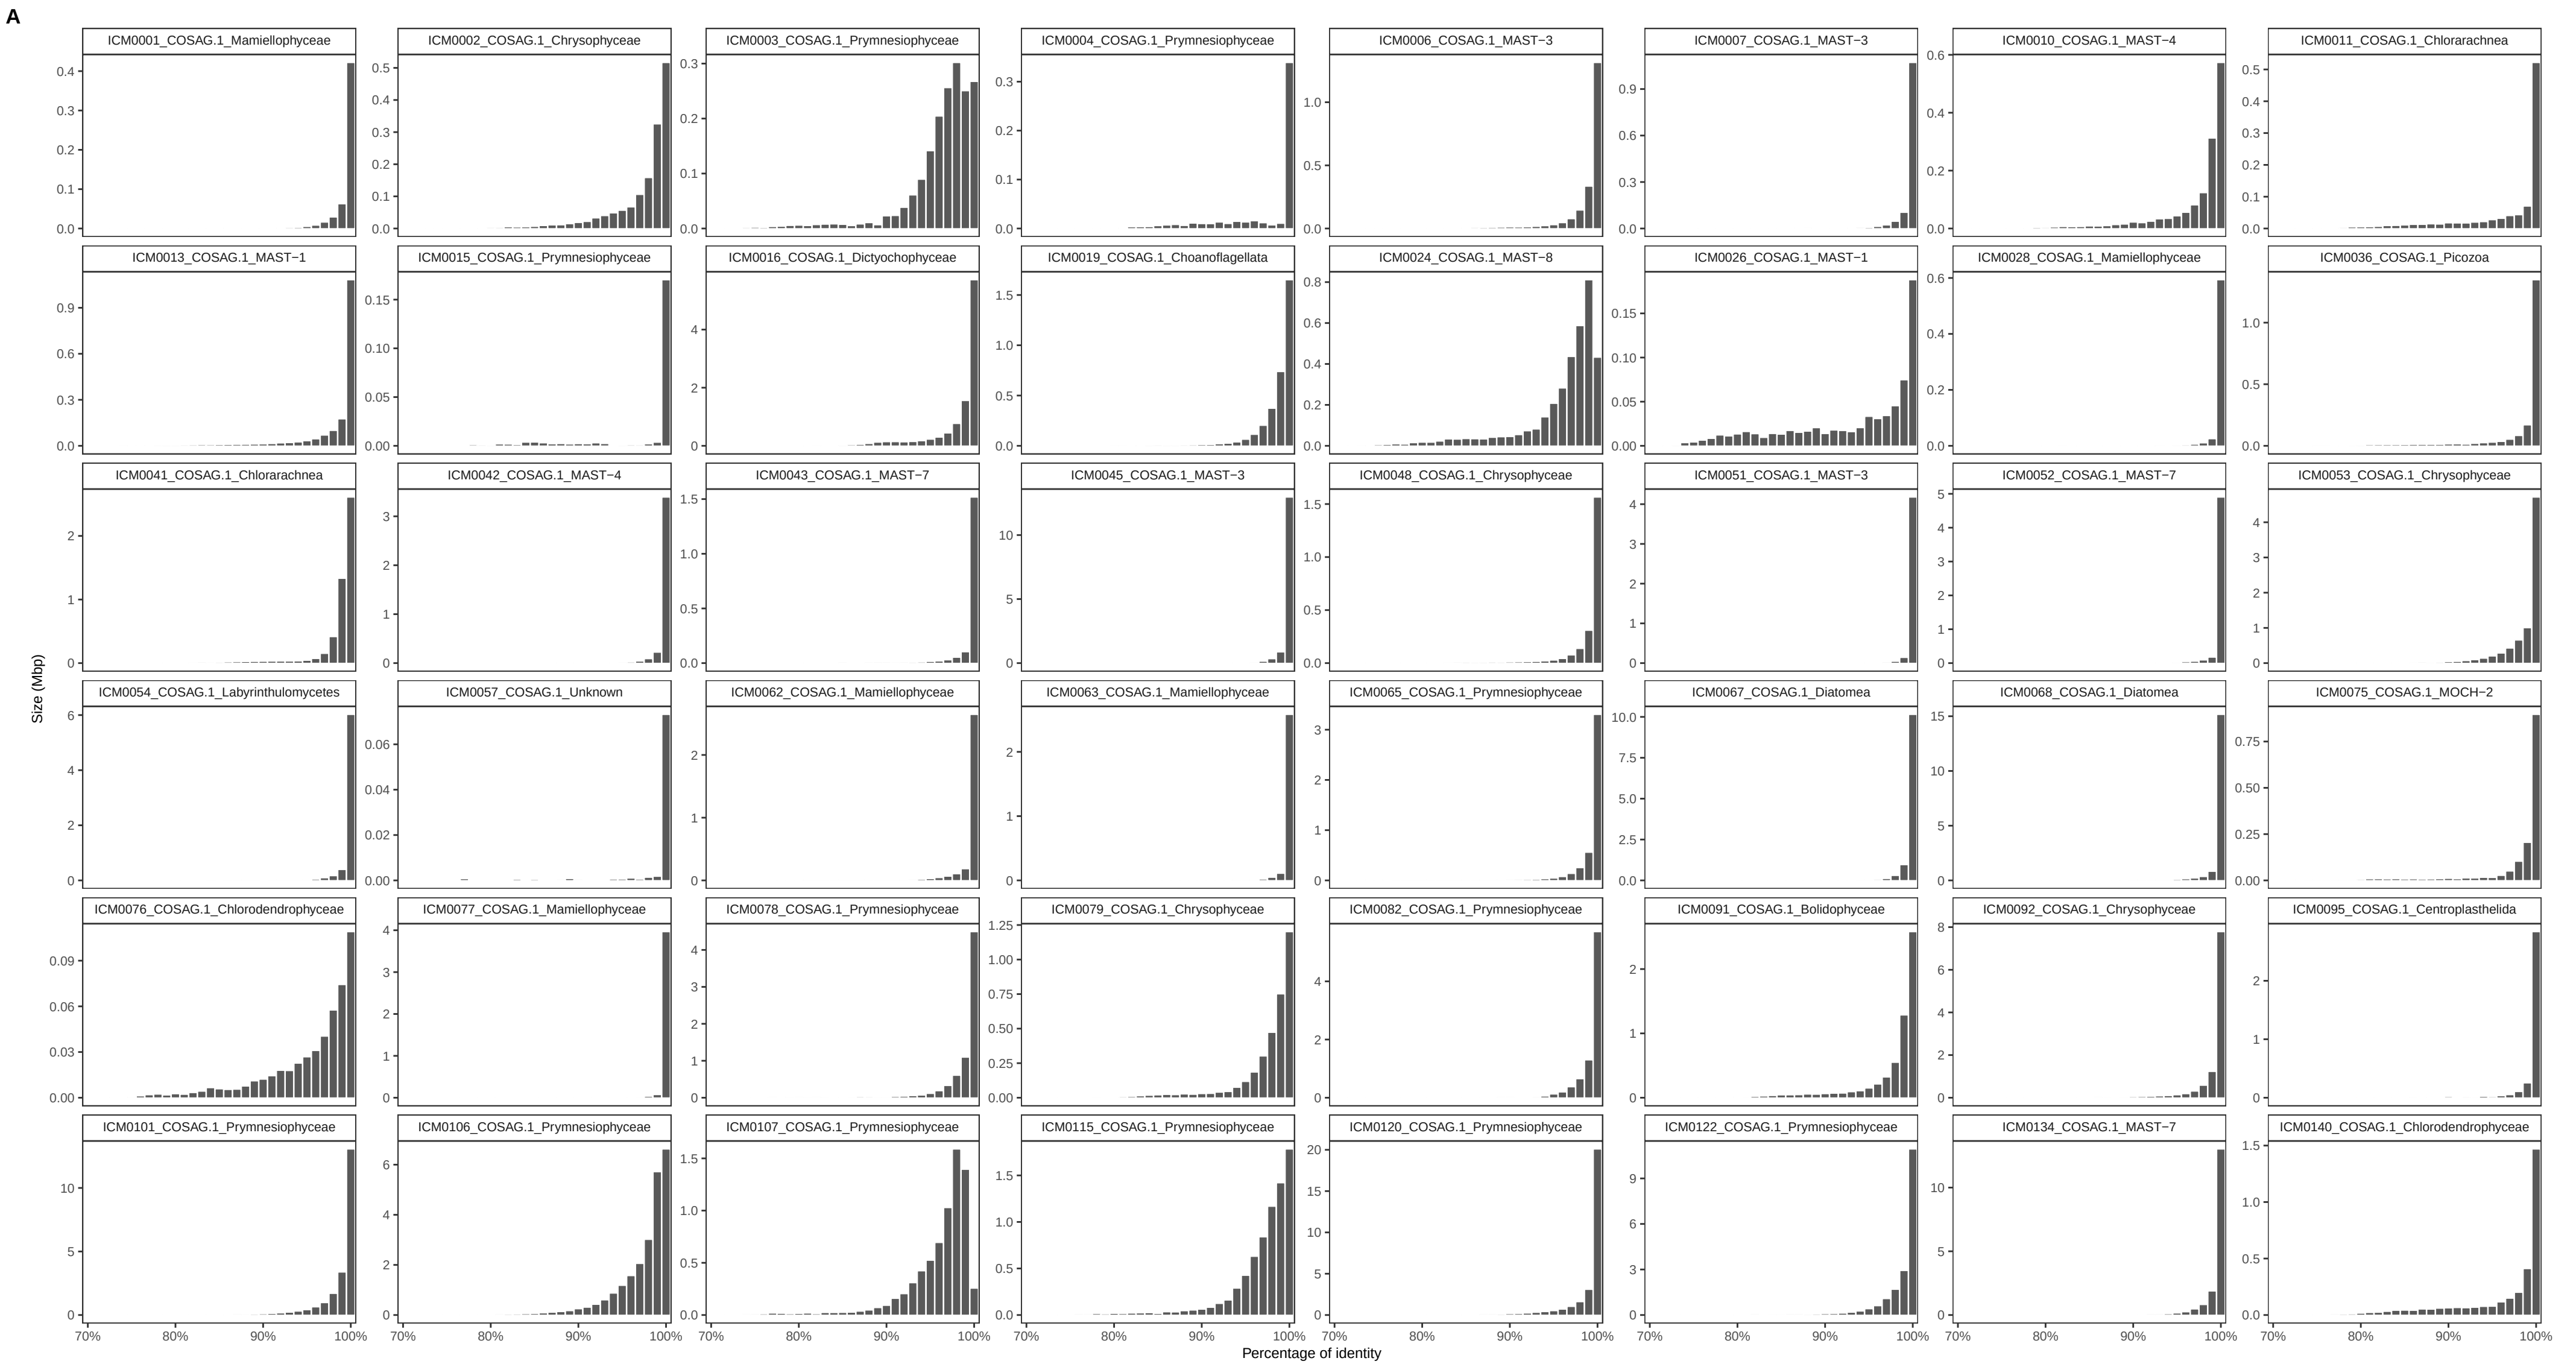

Fig. S1. Genome similarity among SAGs within each co-assembly (A) and between closely distinct genomes (B). Pair-wise average nucleotide identity (ANI) comparisons were calculated by fragmenting the subject genome into 1 kb segments and using BLAST hits with a query ≥ 0.5 kb. The similarity of the queried genome size was distributed in 1% bins histograms. Panels from (b), comparing different genomes, also display the sequence similarity of the 18S rDNA genes (the first 7 cases are those matching the same ASV) and the fraction of the genome that has been compared.
